Lecture 7 - Convex Functions

Definition A function $f : C \to \mathbb{R}$ defined on a convex set $C \subseteq \mathbb{R}^n$ is called convex (or convex over C) if

 $f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) \leq \lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}) \text{ for any } \mathbf{x}, \mathbf{y} \in C, \lambda \in [0, 1].$

1 / 32

Convexity, Strict Convexity and Concavity

- In case where no domain is specified, we naturally assume that f is defined over the entire space ℝⁿ.
- A function f : C → ℝ defined on a convex set C ⊆ ℝⁿ is called strictly convex if

 $f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) < \lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}) \text{ for any } \mathbf{x} \neq \mathbf{y} \in C, \lambda \in (0, 1).$

- ► A function is called concave if -f is convex. Similarly, f is called strictly concave if -f is strictly convex.
- We can also define concavity directly: a function f is concave if and only if for any x, y ∈ C and λ ∈ [0, 1],

 $f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) \ge \lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}).$

Examples of Convex Functions

- Affine Functions. $f(\mathbf{x}) = \mathbf{a}^T \mathbf{x} + b$, where $\mathbf{a} \in \mathbb{R}^n$ and $b \in \mathbb{R}$.
- Norms. g(x) = ||x||.
- Convexity of f: Take $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ and $\lambda \in [0, 1]$. Then

$$f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) = \mathbf{a}^{T}(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) + b$$

= $\lambda(\mathbf{a}^{T}\mathbf{x}) + (1 - \lambda)(\mathbf{a}^{T}\mathbf{y}) + \lambda b + (1 - \lambda)b$
= $\lambda(\mathbf{a}^{T}\mathbf{x} + b) + (1 - \lambda)(\mathbf{a}^{T}\mathbf{y} + b)$
= $\lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}),$

• Convexity of g: Take $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ and $\lambda \in [0, 1]$. Then

$$g(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) = \|\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}\|$$

$$\leq \|\lambda \mathbf{x}\| + \|(1 - \lambda)\mathbf{y}\|$$

$$= \lambda \|\mathbf{x}\| + (1 - \lambda)\|\mathbf{y}\|$$

$$= \lambda g(\mathbf{x}) + (1 - \lambda)g(\mathbf{y}),$$

Jensen's Inequality

Theorem. Let $f : C \to \mathbb{R}$ be a convex function where $C \subseteq \mathbb{R}^n$ is a convex set. Then for any $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_k \in C$ and $\lambda \in \Delta_k$, the following inequality holds:

$$f\left(\sum_{i=1}^k \lambda_i \mathbf{x}_i\right) \leq \sum_{i=1}^k \lambda_i f(\mathbf{x}_i).$$

Proof very similar to the proof that any convex combination of pts. in a convex sets is in the set – see the proof of Theorem 7.5 on pages 118,119 of the book.

The Gradient Inequality

Theorem. Let $f : C \to \mathbb{R}$ be a continuously differentiable function defined on a convex set $C \subseteq \mathbb{R}^n$. Then f is convex over C if and only if

 $f(\mathbf{x}) +
abla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x}) \leq f(\mathbf{y})$ for any $\mathbf{x}, \mathbf{y} \in C$.

Proof.

- Suppose first that f is convex. Let x, y ∈ C and λ ∈ (0, 1]. If x = y, then (1) trivially holds. We will therefore assume that x ≠ y.
- $\blacktriangleright \frac{f(\mathbf{x}+\lambda(\mathbf{y}-\mathbf{x}))-f(\mathbf{x})}{\lambda} \leq f(\mathbf{y}) f(\mathbf{x}).$
- Taking $\lambda \to 0^+$, we obtain

$$f'(\mathbf{x};\mathbf{y}-\mathbf{x}) \leq f(\mathbf{y}) - f(\mathbf{x}).$$

Since f is continuously differentiable, f'(x; y − x) = ∇f(x)^T(y − x), and (1) follows.

(1)

Proof Contd.

- To prove the reverse direction, assume that that the gradient inequality holds.
- ▶ Let $\mathbf{z}, \mathbf{w} \in C$, and let $\lambda \in (0, 1)$. We will show that $f(\lambda \mathbf{z} + (1 \lambda)\mathbf{w}) \leq \lambda f(\mathbf{z}) + (1 \lambda)f(\mathbf{w})$.
- Let $\mathbf{u} = \lambda \mathbf{z} + (1 \lambda) \mathbf{w} \in C$. Then

$$\mathbf{z} - \mathbf{u} = \frac{\mathbf{u} - (1 - \lambda)\mathbf{w}}{\lambda} - \mathbf{u} = -\frac{1 - \lambda}{\lambda}(\mathbf{w} - \mathbf{u}).$$

We have

$$f(\mathbf{u}) + \nabla f(\mathbf{u})^{T}(\mathbf{z} - \mathbf{u}) \leq f(\mathbf{z}),$$

$$f(\mathbf{u}) - \frac{\lambda}{1 - \lambda} \nabla f(\mathbf{u})^{T}(\mathbf{z} - \mathbf{u}) \leq f(\mathbf{w}).$$

Thus,

$$f(\mathbf{u}) \leq \lambda f(\mathbf{z}) + (1 - \lambda)f(\mathbf{w}).$$

The Gradient Inequality for Strictly Convex Functions

Proposition Let $f : C \to \mathbb{R}$ be a continuously differentiable function defined on a convex set $C \subseteq \mathbb{R}^n$. Then f is strictly convex over C if and only if

 $f(\mathbf{x}) + \nabla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x}) < f(\mathbf{y})$ for any $\mathbf{x}, \mathbf{y} \in C$ satisfying $\mathbf{x} \neq \mathbf{y}$

Stationarity \Rightarrow Global Optimality

A direct result of the gradient inequality is that the first order optimality condition $\nabla f(\mathbf{x}^*) = 0$ is sufficient for global optimality.

Proposition Let f be a continuously differentiable function which is convex over a convex set $C \subseteq \mathbb{R}^n$. Suppose that $\nabla f(\mathbf{x}^*) = \mathbf{0}$ for some $\mathbf{x}^* \in C$. Then \mathbf{x}^* is the global minimizer of f over C.

Proof. In class

Convexity of Quadratic Functions with Positive Semidefinite Matrices

Theorem. Let $f : \mathbb{R}^n \to \mathbb{R}$ be the quadratic function given by $f(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + 2\mathbf{b}^T \mathbf{x} + c$ where $\mathbf{A} \in \mathbb{R}^{n \times n}$ is symmetric, $\mathbf{b} \in \mathbb{R}^n$ and $c \in \mathbb{R}$. Then f is (strictly) convex if and only if $\mathbf{A} \succeq \mathbf{0}$ ($\mathbf{A} \succ \mathbf{0}$).

Proof.

▶ The convexity of *f* is equivalent to

 $f(\mathbf{y}) \geq f(\mathbf{x}) +
abla f(\mathbf{x})^T (\mathbf{y} - \mathbf{x})$ for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$

- Same as
 - $\mathbf{y}^T \mathbf{A} \mathbf{y} + 2\mathbf{b}^T \mathbf{y} + c \ge \mathbf{x}^T \mathbf{A} \mathbf{x} + 2\mathbf{b}^T \mathbf{x} + c + 2(\mathbf{A} \mathbf{x} + \mathbf{b})^T (\mathbf{y} \mathbf{x})$ for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$.
- $(\mathbf{y} \mathbf{x})^T \mathbf{A} (\mathbf{y} \mathbf{x}) \ge 0$ for any $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$.
- Equivalent to the inequality $\mathbf{d}^T \mathbf{A} \mathbf{d} \ge 0$ for any $\mathbf{d} \in \mathbb{R}^n$.
- Same as $A \succeq 0$.
- Similar arguments show that strict convexity is equivalent to

 $\mathbf{d}^{\mathsf{T}}\mathbf{A}\mathbf{d} > 0$ for any $\mathbf{0} \neq \mathbf{d} \in \mathbb{R}^{n}$,

namely to $\mathbf{A} \succ \mathbf{0}$.

Amir Beck

"Introduction to Nonlinear Optimization" Lecture Slides - Convex Functions

Illustration

Monotonicity of the Gradient

Theorem. Suppose that f is a continuously differentiable function over a convex set $C \subseteq \mathbb{R}^n$. Then f is convex over C if and only if

 $(\nabla f(\mathbf{x}) - \nabla f(\mathbf{y}))^T (\mathbf{x} - \mathbf{y}) \ge 0$ for any $\mathbf{x}, \mathbf{y} \in C$.

See the proof of Theorem 8.11 on pages 122,123 of the book.

Second-Order Characterization of Convexity

Theorem. Let f be a twice continuously differentiable function over an open convex set $C \subseteq \mathbb{R}^n$. Then f is convex over C if and only if $\nabla^2 f(\mathbf{x}) \succeq \mathbf{0}$ for any $\mathbf{x} \in C$.

Proof.

▶ Suppose that $\nabla^2 f(\mathbf{x}) \succeq \mathbf{0} \ \forall \mathbf{x} \in C$. Let $\mathbf{x}, \mathbf{y} \in C$, then $\exists \mathbf{z} \in [\mathbf{x}, \mathbf{y}] \in C$:

$$f(\mathbf{y}) = f(\mathbf{x}) + \nabla f(\mathbf{x})^{\mathsf{T}}(\mathbf{y} - \mathbf{x}) + \frac{1}{2}(\mathbf{y} - \mathbf{x})^{\mathsf{T}} \nabla^2 f(\mathbf{z})(\mathbf{y} - \mathbf{x}).$$

- $\blacktriangleright (\mathbf{y} \mathbf{x})^T \nabla^2 f(\mathbf{z}) (\mathbf{y} \mathbf{x}) \ge 0 \Rightarrow f(\mathbf{y}) \ge f(\mathbf{x}) + \nabla f(\mathbf{x})^T (\mathbf{y} \mathbf{x}) \Rightarrow f \text{ convex.}$
- ▶ Suppose that f is convex over C. Let $\mathbf{x} \in C$ and let $\mathbf{y} \in \mathbb{R}^n$.
- C is open $\Rightarrow \exists \varepsilon > 0$ such that $\mathbf{x} + \lambda \mathbf{y} \in C \ \forall \lambda \in (0, \varepsilon)$. $f(\mathbf{x} + \lambda \mathbf{y}) > f(\mathbf{x}) + \lambda \nabla f(\mathbf{x})^T \mathbf{y}$.
- $f(\mathbf{x} + \lambda \mathbf{y}) = f(\mathbf{x}) + \lambda \nabla f(\mathbf{x})^T \mathbf{y} + \frac{\lambda^2}{2} \mathbf{y}^T \nabla^2 f(\mathbf{x}) \mathbf{y} + o(\lambda^2 \|\mathbf{y}\|^2).$
- ► Thus, $\frac{\lambda^2}{2} \mathbf{y}^T \nabla^2 f(\mathbf{x}) \mathbf{y} + o(\lambda^2 \|\mathbf{y}\|^2) \ge 0$ for any $\lambda \in (0, \varepsilon)$.
- Dividing by λ^2 , $\frac{1}{2}\mathbf{y}^T \nabla^2 f(\mathbf{x})\mathbf{y} + \frac{o(\lambda^2 ||\mathbf{y}||^2)}{\lambda^2} \ge 0$.
- ► Taking $\lambda \to 0^+$, we have $\mathbf{y}^T \nabla^2 f(\mathbf{x}) \mathbf{y} \ge 0 \forall \mathbf{y} \in \mathbb{R}^n$.
- Hence $\nabla^2 f(\mathbf{x}) \succeq \mathbf{0}$ for any $\mathbf{x} \in C$.

Amir Beck

Convexity of the log-sum-exp function

- ► $f(\mathbf{x}) = \log (e^{x_1} + e^{x_2} + \ldots + e^{x_n}), \quad \mathbf{x} \in \mathbb{R}^n$
- $\begin{array}{l} \bullet \quad \frac{\partial f}{\partial x_i}(\mathbf{x}) = \frac{e^{x_i}}{\sum_{j=1}^n e^{x_j}}, \quad i = 1, 2, \dots, n, \\ \bullet \quad \frac{\partial^2 f}{\partial x_i \partial x_j}(\mathbf{x}) = \begin{cases} -\frac{e^{x_i} e^{x_j}}{\left(\sum_{j=1}^n e^{x_j}\right)^2}, & i \neq j, \\ -\frac{e^{x_i} e^{x_j}}{\left(\sum_{j=1}^n e^{x_j}\right)^2} + \frac{e^{x_i}}{\sum_{j=1}^n e^{x_j}}, & i = j \end{cases} \end{array}$
- We can thus write the Hessian matrix as

$$abla^2 f(\mathbf{x}) = \operatorname{diag}(\mathbf{w}) - \mathbf{w}\mathbf{w}^T, \quad \mathbf{w} = \left(\frac{e^{x_i}}{\sum_{j=1}^n e^{x_j}}\right)_{i=1}^n \in \Delta_n.$$

► For any $\mathbf{v} \in \mathbb{R}^n$: $\mathbf{v}^T \nabla^2 f(\mathbf{x}) \mathbf{v} = \sum_{i=1}^n w_i v_i^2 - (\mathbf{v}^T \mathbf{w})^2 \ge 0$ since defining $s_i = \sqrt{w_i} v_i, t_i = \sqrt{w_i}$, we have

$$(\mathbf{v}^T \mathbf{w})^2 = (\mathbf{s}^T \mathbf{t})^2 \le \|\mathbf{s}\|^2 \|\mathbf{t}\|^2 = \left(\sum_{i=1}^n w_i v_i^2\right) \left(\sum_{i=1}^n w_i\right) = \sum_{i=1}^n w_i v_i^2.$$

▶ Thus, $\nabla^2 f(\mathbf{x}) \succeq \mathbf{0}$ and hence f is convex over \mathbb{R}^n .

Convexity of quad-over-lin

$$f(x_1, x_2) = \frac{x_1^2}{x_2}$$

defined over $\mathbb{R} \times \mathbb{R}_+ = \{(x_1, x_2) : x_2 > 0\}$. In class

Operations Preserving Convexity

 Convexity is preserved under several operations such as summation, multiplication by positive scalars and affine change of variables.

Theorem.

- Let f be a convex function defined over a convex set $C \subseteq \mathbb{R}^n$ and let $\alpha \ge 0$. Then αf is a convex function over C.
- ▶ Let $f_1, f_2, ..., f_p$ be convex functions over a convex set $C \subseteq \mathbb{R}^n$. Then the sum function $f_1 + f_2 + ... + f_p$ is convex over C.
- ▶ Let *f* be a convex function defined on a convex set $C \subseteq \mathbb{R}^n$. Let $\mathbf{A} \in \mathbb{R}^{n \times m}$ and $\mathbf{b} \in \mathbb{R}^n$. Then the function *g* defined by

$$g(\mathbf{y}) = f(\mathbf{A}\mathbf{y} + \mathbf{b}).$$

is convex over the convex set $D = \{ \mathbf{y} \in \mathbb{R}^m : \mathbf{A}\mathbf{y} + \mathbf{b} \in C \}.$

See the proofs of Theorems 7.16 and 7.17 of the book.

Example: Generalized quadratic-over-linear

The generalized quad-over-lin function

$$g(\mathbf{x}) = rac{\|\mathbf{A}\mathbf{x} + \mathbf{b}\|^2}{\mathbf{c}^T \mathbf{x} + d} \quad (\mathbf{A} \in \mathbb{R}^{m imes n}, \mathbf{b} \in \mathbb{R}^m, \mathbf{c} \in \mathbb{R}^n, d \in \mathbb{R})$$

is convex over $D = \{ \mathbf{x} \in \mathbb{R}^n : \mathbf{c}^T \mathbf{x} + d > 0 \}.$ In class

Examples of Convex Functions

$$f(x_1, x_2) = x_1^2 + 2x_1x_2 + 3x_2^2 + 2x_1 - 3x_2 + e^{x_1}$$

$$f(x_1, x_2, x_3) = e^{x_1 - x_2 + x_3} + e^{2x_2} + x_1$$

$$f(x_1,x_2)=-\log(x_1x_2)$$

over \mathbb{R}^2_{++}

In class

Preservation of Convexity under Composition

Theorem. Let $f : C \to \mathbb{R}$ be a convex function defined over the convex set $C \subseteq \mathbb{R}^n$. Let $g : I \to \mathbb{R}$ be a one-dimensional nondecreasing convex function over the interval $I \subseteq \mathbb{R}$. Assume that the image of C under f is contained in $I: f(C) \subseteq I$. Then the composition of g with f defined by

 $h(\mathbf{x}) \equiv g(f(\mathbf{x}))$

is convex over C.

Proof Outline. Let $\mathbf{x}, \mathbf{y} \in C$ and let $\lambda \in [0, 1]$. Then

$$egin{aligned} h(\lambda \mathbf{x} + (1-\lambda)\mathbf{y}) &= g(f(\lambda \mathbf{x} + (1-\lambda)\mathbf{y})) \ &\leq g(\lambda f(\mathbf{x}) + (1-\lambda)f(\mathbf{y})) \ &\leq \lambda g(f(\mathbf{x})) + (1-\lambda)g(f(\mathbf{y})) \ &= \lambda h(\mathbf{x}) + (1-\lambda)h(\mathbf{y}), \end{aligned}$$

thus establishing the convexity of h.

Amir Beck

Examples

In class

Point-Wise Maximum of Convex Functions

Theorem. Let $f_1, f_2, \ldots, f_p : C \to \mathbb{R}$ be p convex functions over the convex set $C \subseteq \mathbb{R}^n$. Then the maximum function

$$f(\mathbf{x}) \equiv \max_{i=1,2,\ldots,p} \{f_i(\mathbf{x})\}$$

is convex over C.

Proof Outline Let $\mathbf{x}, \mathbf{y} \in C$ and $\lambda \in [0, 1]$. Then

$$\begin{aligned} f(\lambda \mathbf{x} + (1 - \lambda) \mathbf{y}) &= \max_{i=1,2,\dots,p} f_i(\lambda \mathbf{x} + (1 - \lambda) \mathbf{y}) \\ &\leq \max_{i=1,2,\dots,p} \{\lambda f_i(\mathbf{x}) + (1 - \lambda) f_i(\mathbf{y})\} \\ &\leq \lambda \max_{i=1,2,\dots,p} f_i(\mathbf{x}) + (1 - \lambda) \max_{i=1,2,\dots,p} f_i(\mathbf{y}) \\ &= \lambda f(\mathbf{x}) + (1 - \lambda) f(\mathbf{y}). \end{aligned}$$

Examples.

- $f(\mathbf{x}) = \max\{x_1, x_2, \dots, x_n\}$ is convex.
- For a given vector x = (x₁, x₂,..., x_n)^T ∈ ℝⁿ, let x_[i] denote the *i*-th largest value in x. For any k ∈ {1, 2, ..., n} the function

$$h_k(\mathbf{x}) = x_{[1]} + x_{[2]} + \ldots + x_{[k]},$$

is convex. why?

"Introduction to Nonlinear Optimization" Lecture Slides - Convex Functions

Preservation of Convexity Under Partial Minimization

Theorem. Let $f : C \times D \to \mathbb{R}$ be a convex function defined over the set $C \times D$ where $C \subseteq \mathbb{R}^m$ and $D \subseteq \mathbb{R}^n$ are convex sets. Let

$$g(\mathbf{x}) = \min_{\mathbf{y}\in D} f(\mathbf{x}, \mathbf{y}), \quad \mathbf{x}\in C,$$

where we assume that the minimum is finite. Then g is convex over C.

Proof. Let $\mathbf{x}_1, \mathbf{x}_2 \in C$ and $\lambda \in [0, 1]$. Take $\varepsilon > 0$. Then $\exists \mathbf{y}_1, \mathbf{y}_2 \in D$:

 $f(\mathbf{x}_1,\mathbf{y}_1) \leq g(\mathbf{x}_1) + \varepsilon, f(\mathbf{x}_2,\mathbf{y}_2) \leq g(\mathbf{x}_2) + \varepsilon.$

By the convexity of f we have

$$\begin{aligned} f(\lambda \mathbf{x}_1 + (1 - \lambda) \mathbf{x}_2, \lambda \mathbf{y}_1 + (1 - \lambda) \mathbf{y}_2) &\leq \lambda f(\mathbf{x}_1, \mathbf{y}_1) + (1 - \lambda) f(\mathbf{x}_2, \mathbf{y}_2) \\ &\leq \lambda (g(\mathbf{x}_1) + \varepsilon) + (1 - \lambda) (g(\mathbf{x}_2) + \varepsilon) \\ &= \lambda g(\mathbf{x}_1) + (1 - \lambda) g(\mathbf{x}_2) + \varepsilon. \end{aligned}$$

Since the above inequality holds for any $\varepsilon > 0$, it follows that $g(\lambda \mathbf{x}_1 + (1 - \lambda)\mathbf{x}_2) \le \lambda g(\mathbf{x}_1) + (1 - \lambda)g(\mathbf{x}_2)$. **Example:** The distance function from a convex set $d_C(\mathbf{x}) \equiv \inf_{\mathbf{y} \in C} \|\mathbf{x} - \mathbf{y}\|$ is convex.

Amir Beck

Level Sets

Definition. Let $f : S \to \mathbb{R}$ be a function defined over a set $S \subseteq \mathbb{R}^n$. Then the level set of f with level α is given by

 $\operatorname{Lev}(f,\alpha) = \{ \mathbf{x} \in S : f(\mathbf{x}) \le \alpha \}.$

Theorem. Let $f : C \to \mathbb{R}$ be a convex function over the convex set $C \subseteq \mathbb{R}^n$. Then for any $\alpha \in \mathbb{R}$ the level set $\text{Lev}(f, \alpha)$ is convex.

Proof.

- Let $\mathbf{x}, \mathbf{y} \in \text{Lev}(f, \alpha)$ and $\lambda \in [0, 1]$.
- Then $f(\mathbf{x}), f(\mathbf{y}) \leq \alpha$. Hence,

 $f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) \le \lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}) \le \lambda \alpha + (1 - \lambda)\alpha = \alpha,$

► $\lambda \mathbf{x} + (1 - \lambda) \mathbf{y} \in \text{Lev}(f, \alpha)$, and we have established the convexity of $\text{Lev}(f, \alpha)$.

Quasi-Convex Functions

▶ Definition. A function $f : C \to \mathbb{R}$ defined over the convex set $C \subseteq \mathbb{R}^n$ is called quasi-convex if for any $\alpha \in \mathbb{R}$ the set $\text{Lev}(f, \alpha)$ is convex.

Examples:

f(*x*) = √|*x*|. *f*(*x*) = ^{*a*^T*x*+*b*}/_{*c*^T*x*+*d*}, over *C* = {*x* ∈ ℝⁿ : *c*^T*x* + *d* > 0}. where *a*, *c* ∈ ℝⁿ and *b*, *d* ∈ ℝ.

Continuity of Convex Functions

Theorem. Let $f : C \to \mathbb{R}$ be a convex function defined over a convex set $C \subseteq \mathbb{R}^n$. Let $\mathbf{x}_0 \in int(C)$. Then there exist $\varepsilon > 0$ and L > 0 such that $B[\mathbf{x}_0, \varepsilon] \subseteq C$ and

 $|f(\mathbf{x}) - f(\mathbf{x}_0)| \le L \|\mathbf{x} - \mathbf{x}_0\|$ for any $\mathbf{x} \in B[\mathbf{x}_0, \varepsilon]$

Proof.

- Take $\varepsilon > 0$ such that $B_{\infty}[\mathbf{x}_0, \varepsilon] \equiv \{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x} \mathbf{x}_0\|_{\infty} \le \varepsilon\} \subseteq C$.
- Let $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_{2^n}$ be the 2^n extreme points of $B_{\infty}[\mathbf{x}_0, \varepsilon]$.
- For any $\mathbf{x} \in B_{\infty}[\mathbf{x}_0, \varepsilon]$ there exists $\lambda \in \Delta_{2^n}$ such that $\mathbf{x} = \sum_{i=1}^{2^n} \lambda_i \mathbf{v}_i$. By Jensen's inequality,

$$f(\mathbf{x}) = f\left(\sum_{i=1}^{2^n} \lambda_i \mathbf{v}_i\right) \leq \sum_{i=1}^{2^n} \lambda_i f(\mathbf{v}_i) \leq M_i$$

where $M = \max_{i=1,2,\dots,2^n} f(\mathbf{v}_i)$.

 $\blacktriangleright B_2[\mathbf{x}_0,\varepsilon] = B[\mathbf{x}_0,\varepsilon] = \{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x} - \mathbf{x}_0\|_2 \le \varepsilon\} \subseteq B_\infty[\mathbf{x}_0,\varepsilon].$

• We therefore conclude that $f(\mathbf{x}) \leq M$ for any $\mathbf{x} \in B[\mathbf{x}_0, \varepsilon]$.

Continuity of Convex Functions Contd.

• Let $\mathbf{x} \in B[\mathbf{x}_0, \varepsilon]$ be such that $\mathbf{x} \neq \mathbf{x}_0$. Define

$$\mathbf{z} = \mathbf{x}_0 + \frac{1}{lpha} (\mathbf{x} - \mathbf{x}_0), \quad \alpha = \frac{1}{\varepsilon} \|\mathbf{x} - \mathbf{x}_0\|$$

- Then obviously α ≤ 1 and z ∈ B[x₀, ε], and in particular f(z) ≤ M.
 x = αz + (1 − α)x₀.
- Consequently,

$$f(\mathbf{x}) \leq \alpha f(\mathbf{z}) + (1-\alpha)f(\mathbf{x}_0) \leq f(\mathbf{x}_0) + \alpha (M - f(\mathbf{x}_0)) = f(\mathbf{x}_0) + \frac{M - f(\mathbf{x}_0)}{\varepsilon} \|\mathbf{x} - \mathbf{x}_0\|.$$

- ▶ Thus, $f(\mathbf{x}) f(\mathbf{x}_0) \leq L \|\mathbf{x} \mathbf{x}_0\|$, where $L = \frac{M f(\mathbf{x}_0)}{\varepsilon}$.
- We need to show that $f(\mathbf{x}) f(\mathbf{x}_0) \ge -L \|\mathbf{x} \mathbf{x}_0\|$.
- Define $\mathbf{u} = \mathbf{x}_0 + \frac{1}{\alpha}(\mathbf{x}_0 \mathbf{x})$. Since $\mathbf{u} \in B[\mathbf{x}_0, \varepsilon]$, then $f(\mathbf{u}) \leq M$.

$$\mathbf{x} = \mathbf{x}_0 + \alpha(\mathbf{x}_0 - \mathbf{u}). \text{ I herefore,}$$

$$f(\mathbf{x}) = f(\mathbf{x}_0 + \alpha(\mathbf{x}_0 - \mathbf{u})) \ge f(\mathbf{x}_0) + \alpha(f(\mathbf{x}_0) - f(\mathbf{u}))$$

$$(f(\mathbf{x}_0) = M - f(\mathbf{x}_0) + \alpha(f(\mathbf{x}_0) - f(\mathbf{u}))$$

$$= f(\mathbf{x}_0) - \frac{\varepsilon}{\varepsilon} \|\mathbf{x} - \mathbf{x}_0\|$$
$$= f(\mathbf{x}_0) - L \|\mathbf{x} - \mathbf{x}_0\|$$

Amir Beck

"Introduction to Nonlinear Optimization" Lecture Slides - Convex Functions

Existence of Directional Derivatives of Convex Functions

Theorem. Let $f : C \to \mathbb{R}$ be a convex function over the convex set $C \subseteq \mathbb{R}^n$. Let $\mathbf{x} \in int(C)$. Then for any $\mathbf{d} \neq \mathbf{0}$, the directional derivative $f'(\mathbf{x}; \mathbf{d})$ exists.

Proof.

Let x ∈ int(C) and let d ≠ 0. Then the directional derivative (if exists) is the limit

$$\lim_{t \to 0^+} \frac{g(t) - g(0)}{t} \quad (g(t) = f(\mathbf{x} + t\mathbf{d}))$$
(2)

- Defining $h(t) = \frac{g(t)-g(0)}{t}$, (2) is the same as $\lim_{t\to 0^+} h(t)$.
- We will take an $\varepsilon > 0$ for which $\mathbf{x} + t\mathbf{d}, \mathbf{x} t\mathbf{d} \in C$ for all $t \in [0, \varepsilon]$.
- ▶ Let $0 < t_1 < t_2 \le \varepsilon$. Then $f(\mathbf{x} + t_1 \mathbf{d}) \le \left(1 \frac{t_1}{t_2}\right) f(\mathbf{x}) + \frac{t_1}{t_2} f(\mathbf{x} + t_2 \mathbf{d})$.
- Consequently, $\frac{f(\mathbf{x}+t_1\mathbf{d})-f(\mathbf{x})}{t_1} \leq \frac{f(\mathbf{x}+t_2\mathbf{d})-f(\mathbf{x})}{t_2}$.
- Thus, h(t₁) ≤ h(t₂) ⇒ h is monotone nondecreasing over ℝ₊₊. All that is left is to show that it is bounded below over (0, ε].

Proof Contd.

Hence,

• Take
$$0 < t \leq \varepsilon$$
. Note that

$$\mathbf{x} = rac{arepsilon}{arepsilon+t} (\mathbf{x} + t\mathbf{d}) + rac{t}{arepsilon+t} (\mathbf{x} - arepsilon \mathbf{d}).$$

$$f(\mathbf{x}) \leq rac{arepsilon}{arepsilon+t}f(\mathbf{x}+t\mathbf{d}) + rac{t}{arepsilon+t}f(\mathbf{x}-arepsilon\mathbf{d}).$$

After some rearrangement of terms,

$$h(t) = \frac{f(\mathbf{x} + t\mathbf{d}) - f(\mathbf{x})}{t} \ge \frac{f(\mathbf{x}) - f(\mathbf{x} - \varepsilon\mathbf{d})}{\varepsilon}$$

- h is bounded below over (0, ε].
- Since h is nondecreasing and bounded below over (0, ε], the limit lim_{t→0+} h(t) exists ⇒ the directional derivative f'(x; d) exists.

Extended Real-Valued Functions

- ▶ Until now we have discussed functions that are real-valued, meaning that they take their values in $\mathbb{R} = (-\infty, \infty)$.
- We will now consider functions that take their values in ℝ ∪ {∞} = (-∞, ∞]. Such functions are called extended real-valued functions.
- ▶ **Example:** the indicator function: given a set $S \subseteq \mathbb{R}^n$, the indicator function $\delta_S : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is given by

$$\delta_{\mathcal{S}}(\mathbf{x}) = \begin{cases} 0 & \text{if } \mathbf{x} \in \mathcal{S}, \\ \infty & \text{if } \mathbf{x} \notin \mathcal{S}. \end{cases}$$

The effective domain of an extended real-valued function is the set of vectors for which the function takes a real value:

$$\operatorname{dom}(f) = \{ \mathbf{x} \in \mathbb{R}^n : f(\mathbf{x}) < \infty \}.$$

▶ An extended real-valued function $f : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is called proper if is not always equal to infinity, meaning that there exists $\mathbf{x}_0 \in \mathbb{R}^n$ such that $f(\mathbf{x}_0) < \infty$.

Amir Beck

Extended Real-Valued Functions Contd.

An extended real-valued function is convex if for any x, y ∈ ℝⁿ and λ ∈ [0, 1] the following inequality holds:

 $f(\lambda \mathbf{x} + (1 - \lambda)\mathbf{y}) \le \lambda f(\mathbf{x}) + (1 - \lambda)f(\mathbf{y}),$

where we use the usual arithmetic rules with ∞ such as

 $\begin{array}{rcl} a + \infty & = & \infty \text{ for any } a \in \mathbb{R}, \\ a \cdot \infty & = & \infty \text{ for any } a \in \mathbb{R}_{++}. \end{array}$

In addition, we have the much less obvious rule that $0 \cdot \infty = 0$.

- It is easy to show that an extended real-valued function is convex iff dom(f) is a convex set and the restriction of f to its effective domain is a convex real-valued function over dom(f).
- As an example, the indicator function δ_C(·) of a set C ⊆ ℝⁿ is convex if and only if C is a convex set.

The Epigraph

Definition. Let f : ℝⁿ → ℝ ∪ {∞}. Then its epigraph epi(f) ∈ ℝⁿ⁺¹ is defined to be the set

 $\operatorname{epi}(f) = \{(\mathbf{x}; t) : f(\mathbf{x}) \le t\}.$

It is not difficult to show that an extended real-valued function f is convex if and only if its epigraph set epi(f) is convex.

Amir Beck

Preservation of Convexity Under Supremum

Theorem. Let $f_i : \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ be an extended real-valued convex functions for any $i \in I$ (I being an arbitrary index set). Then the function $f(\mathbf{x}) = \sup_{i \in I} f_i(\mathbf{x})$ is an extended real-valued convex function.

Proof. f_i convex for all $i \Rightarrow epi(f_i)$ convex $\Rightarrow epi(f) = \bigcap_{i \in I} epi(f_i)$ convex \Rightarrow $f(\mathbf{x}) = \sup_{i \in I} f_i(\mathbf{x})$ is convex.

▶ **Support Functions**. Let $S \subseteq \mathbb{R}^n$. The support function of *S* is the function

$$\sigma_{\mathcal{S}}(\mathbf{x}) = \sup_{\mathbf{y}\in\mathcal{S}} \mathbf{x}^{\mathsf{T}} \mathbf{y}.$$

The support function is a convex function (regardless of whether S is convex or not).

Maximum of a Convex Fun. over a Compact Convex Set

Theorem. Let $f : C \to \mathbb{R}$ be convex over the nonempty convex and compact set $C \subseteq \mathbb{R}^n$. Then there exists at least one maximizer of f over C that is an extreme point of C.

Proof.

- Let x* be a maximizer of f over C. If x* is an extreme point of C, then the result is established. Otherwise,
- ▶ By Krein-Milman, $C = \operatorname{conv}(\operatorname{ext}(C)) \Rightarrow \exists \mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_k \in \operatorname{ext}(C)$ and $\lambda \in \Delta_k$ s.t.

$$\mathbf{x}^* = \sum_{i=1}^k \lambda_i \mathbf{x}_i.$$

By convexity of f,

$$f(\mathbf{x}^*) \leq \sum_{i=1}^k \lambda_i f(\mathbf{x}_i),$$

$$\blacktriangleright \sum_{i=1}^{k} \lambda_i (f(\mathbf{x}_i) - f(\mathbf{x}^*)) \ge 0 \Rightarrow f(\mathbf{x}_i) = f(\mathbf{x}^*) \text{ (why?)}$$
